

# AirLoft user manual

## How to run the project

First, ``cd`` to the root directory of the project, then run ``npm install`` to install all node modules.

Then, open a new tab in terminal and run ``mongod`` to open a local mongo database, then back to the first terminal tab and run ``nodemon`` to start listening to “localhost: 3000/” at your local computer.

since TA's local computer doesn't store our user-generated data, we recommend to directly go to the following URL(<https://frozen-ocean-17990.herokuapp.com/>) to check the live website, where we load in the user information from live mongolab database.

we recommend to run the project in Chrome or Firefox, since this website needs to call HTML5 API functions, so it will send a request to your browser and ask for permission. It can run in Safari, but it needs the user to go to “privacy” panel under Mac's setting window to activate the location service.
